Abstract

Advances in GaN-HEMT devices have encouraged the development of power converters at megahertz-level. However, inductors for high-frequency power converters require innovative approaches to overcome challenging constraints in both power and frequency. In this context, this paper presents an extension of the Parseval's theorem for the inductor analysis based on the energy conservation principle in the time and the frequency domains. Our approach aims to provide insights about the inductor power losses using high-frequency parameters and the inductor current harmonics. The proposed approach disaggregates the power losses in the frequency-domain for the inductor power signals in the time-domain. Main findings from the presented methodology provide useful selection criteria for inductors in power converters given parameters of quality factor (Q) and Self Resonance Frequency (SRF). Simulation results show the impact of the inductor behavior on the switching losses. An experimental setup validates the proposed approach. A high-frequency boost converter is presented as a study case.

Keywords: Power Inductor, Quality Factor, Self Resonance Frequency, Boost Converter, GaN-HEMT.

1. Introduction

¹ Traditional analysis of power converters requires design tools intended to
² deal with operation frequencies around hundreds of kilohertz [1]. However,
³ outstanding advances in Gallium Nitride - High Electron Mobility Transis-
⁴ tors (GaN-HEMTs) enlarge the operation condition of power converters to

*Corresponding author: alonso.gutierrezgaleano@cea.fr

5 the range of megahertz [2][3]. Indeed, this extended bandwidth requires in-
6 novative design methodologies to achieve a trade-off between high-frequency
7 and high-power conditions [4]. Additionally, these new generation of power
8 converters should incorporate power inductors with both high current han-
9 dling and high operation frequency [5][6].

10

11 As result, high-frequency parameters become more and more important
12 for the analysis and selection of inductors during the design process of power
13 converters [7][8]. Usually, applications of inductors in high-frequency take
14 into account the manufacturer parameters of Self Resonance Frequency (*SRF*)
15 and quality factor (*Q*). These *SRF* and *Q* parameters allow describing the
16 inductor operation bandwidth and the associated power losses. However,
17 these inductor parameters are few analyzed in the conventional design of
18 power converters at kilohertz-level. Conversely, operation at megahertz-level
19 should include the *SRF* and *Q* parameters in the design stage.

20

21 Additionally, the switching improvements provided by GaN-HEMTs can
22 extend the operation frequency of power inductors to levels usually dedi-
23 cated to radio-frequency applications. However, manufacturing constrains
24 associated to ferromagnetic cores limit the scope of power inductors in high-
25 frequency applications [9]. Therefore, manufacturing features and power-
26 frequency behavior require a suitable trade-off to improve the inductor per-
27 formance in high-frequency power converters [10][11].

28

29 In this context, we proposed an innovative approach using the Parseval's
30 theorem as a means to associate the power losses in the time-domain and the
31 inductor behavior in the frequency-domain. The developed framework aims
32 to be complementary to conventional and well known methodologies for the
33 inductor selection and design of power converters. This approach provides
34 insights about the impact of the quality factor (*Q*) and the Self Resonance
35 Frequency (*SRF*) on the inductor current harmonics and the power losses.
36 Simulation results suggest suitable criteria for a trade-off between the quality
37 factor (*Q*) and the power losses given feasible manufacturing features. Fur-
38 thermore, this paper proposes an inductor model incorporating the *Q* and
39 *SRF* parameters into a circuital model useful for the analysis of power con-
40 verters.

41

42 This paper is organized as follows. Section 2 describes the power and fre-

43 quency behavior of power inductors considering high-frequency parameters.
 44 Section 3 presents the theoretical approach based on the Parseval's theorem
 45 to study the relation between power and frequency. Section 4 describes the
 46 proposed inductor model including SRF and Q parameters. Section 5 ex-
 47 plains in detail the experimental setup to validate the proposed approach.
 48 Finally, an experimental high-frequency boost converter is implemented.

49 2. Power inductor behavior in high-frequency

50 This section describes the inductor behavior in a high-frequency power
 51 converter taking into account the quality factor (Q) and the Self Resonance
 52 Frequency (SRF). A high-frequency boost converter is presented as an il-
 53 lustrative example.

54
 55 Fig. 1 shows the designed boost converter as a study case using a com-
 56 mercial reference of a power inductor. The switching frequency is set to
 57 30MHz to take advantage of the switching characteristics of GaN-HEMTs.
 58 This boost converter increases the voltage from 200V to 400V with output
 59 power of 400W and load of 400Ω . In this design, the inductor is set to
 60 $8.2\mu\text{H}$ and the output capacitance is set to 220pF. Furthermore, the studied
 61 converter focuses on the inductor performance considering ideal the other
 62 components to avoid their influence in the developed analysis.

63

Figure 1: High-frequency boost converter with actual inductor and ideal associated components.

64 Fig. 2 depicts the frequency behavior of the associated inductor losses
 65 R_f and the quality factor Q_f for the power inductor of $8.2\mu\text{H}$ used in the
 66 designed boost converter. Additionally, Fig. 2 shows the SRF of the stud-
 67 ied power inductor. The inductive characteristics prevail in the region of

68 frequencies lower than the SRF and the capacitive characteristics prevail
 69 in frequencies higher than the SRF . R_f and Q_f of Fig. 2 are calculated
 70 using the inductor model provided by the manufacturer. The R_f and Q_f
 71 parameters depend on the actual inductor impedance $Z = |Z| \angle \theta$. The as-
 72 sociated losses R_f are defined as the real part of the inductor impedance
 73 by $R_f = |Z| \cos \theta$. The quality factor Q_f expresses the relation between the
 74 stored and dissipated energy. The quality factor Q_f in an inductor is given
 75 by $Q_f = X_L/R_f = \tan \theta_L$, where $X_L = |Z| \sin \theta$.
 76

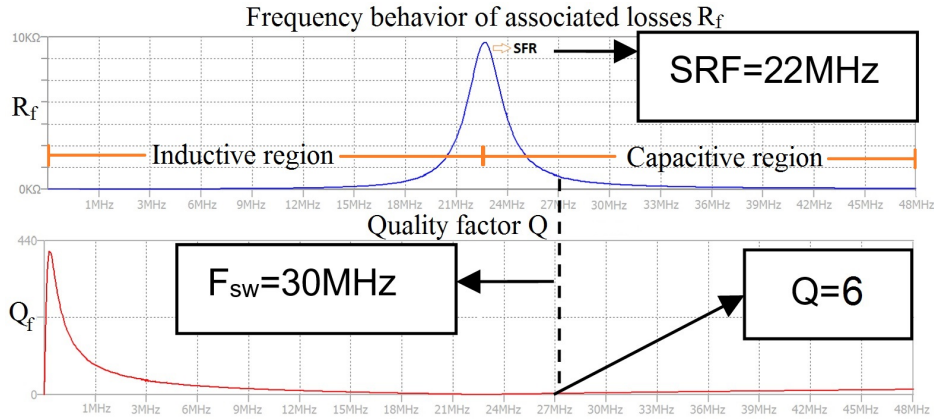

Figure 2: Frequency behavior of R_f and Q_f for the power inductor used in the designed boost converter.

77 The power inductor under study accomplish the requirements of induc-
 78 tance and current in the range of KHz. However, it has a low performance
 79 in the range of MHz as shown in Fig. 2. The proposed analysis intentionally
 80 begins with this unsuitable inductor to assess and understand the influence
 81 of the high-frequency parameters in the inductor performance. This analysis
 82 is the first step to define selection criteria for high-frequency power inductors
 83 with a suitable trade-off between performance and feasibility.

84
 85 Fig. 3 shows the simulation results comparing the inductor current in the
 86 case of an ideal inductor in series with a low resistance and the manufacturer
 87 model for the studied inductor. In addition, Fig. 4 illustrates the current har-
 88 monic spectrum of the inductor under analysis. Results from Fig. 2 to Fig.
 89 4 show that the unsuitable SRF causes distortion in the inductor current
 90 given the harmonics in the capacitive region beyond of the SRF of 22MHz.

Figure 3: Inductor current. Color nomenclature: blue – ideal inductor in series with a low resistance, red – inductor under study.

Figure 4: Current harmonic spectrum for the studied inductor.

91 In addition, the low Q parameter causes important power losses in compari-
 92 son with the ideal inductor in series with a low resistance. These power losses
 93 in the time-domain are associated to the interactions between the inductor
 94 harmonics and the inductor behavior in high-frequency. Next section will
 95 discuss these interactions using the Parseval's theorem, which describes the
 96 energy conservation in the frequency-domain and the time-domain.

97

98 **3. Parseval's theorem approach**

99 As described in the previous study case, the wrong selection of the power
 100 inductor leads to low signal quality and higher losses in high-frequency power
 101 converters. As a result, the following theoretical approach provides insights
 102 about the relation between power and frequency of inductors suitable for
 103 high-frequency power converters.

104

105 Considering the approach described in [12] and defining the inductor cur-
 106 rent $i(t)$ and the inductor voltage $v(t)$, the electrical energy U_L for an inductor
 107 in the time-domain is given by eq.(1).

108

$$U_L = \int_{-\infty}^{\infty} p(t) dt = \int_{-\infty}^{\infty} i(t)v(t) dt \quad (1)$$

109

110

111 In the frequency-domain, the convolution theorem applied to the power
 112 expression $i(t)v(t)$ of eq.(1) is given by eq.(2),

113

$$\mathcal{F}\{i(t)v(t)\} = I(f) * V(f) \quad (2)$$

114

115

116 where $I(f), V(f)$ are the complex valued Fourier transforms. \mathcal{F} denotes
 117 Fourier transform, and $*$ denotes convolution. By definitions of Fourier trans-
 118 form \mathcal{F} and convolution, the eq.(2) becomes eq.(3),

119

$$\int_{-\infty}^{\infty} i(t)v(t) e^{-j2\pi\sigma} dt = \int_{-\infty}^{\infty} I(f)V(\sigma - f) df \quad (3)$$

120

121

122 the evaluation of the Fourier transform at the origin ($\sigma = 0$) equals the
 123 integrals over all their domains [REF REF]. Thus, the electrical energy U_L
 124 from eq.(1) can be expressed by eq.(4), where $\overline{V(f)}$ is the complex conju-
 125 gated of $V(f)$,

126

$$\int_{-\infty}^{\infty} i(t)v(t) dt = \int_{-\infty}^{\infty} I(f)\overline{V(f)} df \quad (4)$$

127

128

129

therefore,

130

$$\int_{-\infty}^{\infty} i(t)v(t) dt = \int_{-\infty}^{\infty} I(f)\overline{[I(f)Z(f)]} df = \int_{-\infty}^{\infty} I(f)^2\overline{Z(f)} df \quad (5)$$

131

132

133

134

given that $Z(f) = R_f + jX_L$ is the complex impedance of the inductor and X_L is an odd function [12],

135

$$\int_{-\infty}^{\infty} i(t)v(t) dt = \int_{-\infty}^{\infty} |I(f)|^2 (R_f - jX_L) df = \int_{-\infty}^{\infty} |I(f)|^2 R_f df \quad (6)$$

136

137

138

139

140

141

142

143

144

145

the result in eq.(6) illustrates the energy conservation between the time and the frequency domains. Therefore, eq.(6) can be seen as an extension of the Parseval's theorem [12]. The physical interpretation of eq.(6) is that the total energy U_L of the inductor can be calculated by integrating power over time or by the spectral power across frequency known the current and the associated losses. The Parseval's identity define the relation between the average power of a signal $h(t)$ and their Fourier coefficients as,

$$\frac{1}{T} \int_{-T/2}^{T/2} |h(t)|^2 dt = \sum_{n=-\infty}^{\infty} |C_n|^2 \quad (7)$$

146

147

148

149

therefore, the average inductor power can be expressed from eq.(6) by,

$$P_{AVG} = \frac{1}{T} \int_0^T i(t)v(t) dt = \sum_{n=0}^N I_n^2 R_f \quad (8)$$

150

151

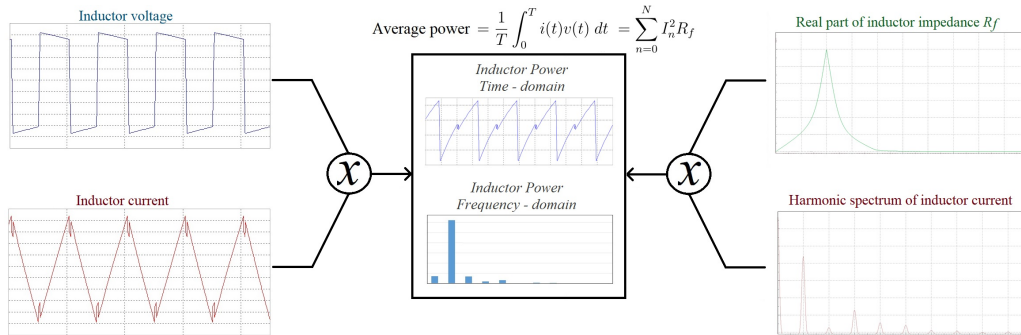

Figure 5: Extension of Parseval's theorem for the inductor analysis in power converters.

152 As a result, the average inductor power depends on the current harmonics
 153 I_n and the associated inductor losses R_f from the real part of the inductor
 154 impedance in the frequency-domain. Fig. 5 depicts an illustrative interpretation
 155 of the developed concept about the equivalence between the power
 156 in the time and the frequency domains. The right side criterion of eq.(8)
 157 is applied to the designed boost converter by means of the associated inductor
 158 losses R_f and the current harmonics (see Fig. 2 and Fig. 4). The results
 159 for the average power in the time and frequency domains are summarized in
 160 Fig. 6 and Fig. 7. These results agree with the expected energy conservation
 161 criterion.

162

163 Fig. 7 depicts the distribution of power losses in the frequency domain.
 164 Results in Fig. 7 show that harmonics higher than eight times the switching
 165 frequency F_{sw} have a negligible impact on the power losses. In addition, this
 166 figure allows highlighting the contribution to the power losses of the current
 167 at the switching frequency. In this case, the higher losses are given at
 168 the switching frequency F_{sw} despite of the very high ratio between the DC
 169 current and the current at F_{sw} . The relative high value of R_f explains this
 170 power losses at the switching frequency F_{sw} . Therefore, it is fundamental
 171 to increase the quality factor Q to decrease the R_f losses at the switching
 172 frequency F_{sw} in order to improve the global inductor efficiency.

173

174 Fig. 8 shows the relation of the power losses in the time domain against
 175 the quality factor at the switching frequency $Q(F_{sw})$,

Figure 6: Inductor power in the time-domain.

Figure 7: Inductor power in the frequency-domain.

176

$$Q(F_{sw}) = \frac{X_L(F_{sw})}{R_f(F_{sw})} \tag{9}$$

177

178

179

180

181

182

183

184

The plot is calculated from eq.(8) by assuming that the highest contribution to the power losses comes from the fundamental frequency at the switching frequency. To plot this figure, the SRF is assumed to be eight times the switching frequency F_{sw} and the Q factor is evaluated at 30MHz for a fixed current spectrum. Results in Fig. 8 allow concluding that increasing considerably the Q factor has low impact in the power losses since the

185 reduction in power losses becomes negligible. Therefore, it is necessary an
 186 approach to the suitable selection of the Q factor. In this context, the next
 187 section will propose a circuitual model to include the SRF and Q parameters
 188 in the converter design process to assess their impact in the converter per-
 189 formance and to further inductor selection or manufacturing.

190

Figure 8: Inductor losses and quality factor Q_{sw} at the switching frequency F_{sw} .

191 4. Proposed inductor model including SRF and Q

192 Currently, development of power electronics requires power inductors able
 193 to operate in high-frequency with high current capabilities. Therefore, the
 194 manufacturing specifications of SRF and Q should be useful to both power
 195 converter designers and inductor manufactures. As a result, this section pro-
 196 vides a framework to integrate these parameters in the design process of
 197 power converters.

198

199 Fig. 9 describes a circuitual model for actual inductors usually used for
 200 the circuit simulation tools. This model includes an ideal inductor L , a series
 201 resistance R_s , a parasite capacitance C_p , and a parallel losses resistance R_p .

202

203 For the inductor model of Fig. 9, the inductor impedance Z is given by
 204 the eq.(10) at the switching frequency F_{sw} and $\omega_{sw} = 2\pi F_{sw}$,

205

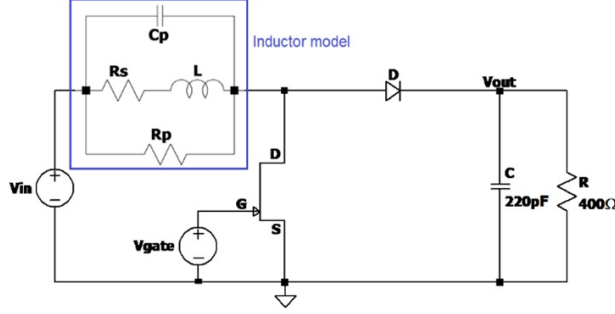

Figure 9: Boost converter with inductor model.

$$Z = \frac{1}{\frac{1}{R_p} + \frac{1 - \omega_{sw}^2 LC_p + j\omega_{sw} C_p R_s}{R_s + j\omega_{sw} L}} \quad (10)$$

206

207

208 considering the real and imaginary parts of Z and solving for Q_{sw} , where
 209 Q_{sw} is defined as the quality factor at the switching frequency $Q(F_{sw})$, we
 210 have,

211

$$Q_{sw} = \frac{Im(Z)}{Re(Z)} = \frac{-R_p (\omega_{sw} C_p R_s^2 - \omega_{sw} L + \omega_{sw}^3 C_p L^2)}{R_s^2 + \omega_{sw}^2 L^2 + R_p R_s} \quad (11)$$

212

213

214 solving for R_p ,

215

$$R_p = \frac{Q_{sw} (R_s^2 + \omega_{sw}^2 L^2)}{-\omega_{sw}^3 C_p L^2 + \omega_{sw} L - \omega_{sw} C_p R_s^2 - Q_{sw} R_s} \quad (12)$$

216

217

218 Additionally, the SFR is defined by the inductor resonance frequency.
 219 Thus, the C_p capacitance is given by,

220

$$C_p = \frac{1}{(2\pi)^2 (SFR)^2 L} \quad (13)$$

221

222

223 Eq.(12) and eq.(13) allow including in the circuitual inductor model the
224 high-frequency parameters of Self Resonance Frequency (SRF) and the qual-
225 ity factor at the switching frequency Q_{sw} . Therefore, these expressions are
226 useful to simulate and evaluate the impact of the SRF and Q parameters on
227 the power converter performance.

228

229 As illustrative example, the boost converter of Fig. 9 is simulated for
230 $F_{sw}=30\text{MHz}$, $L=8.2\mu\text{H}$, and $R_s=0.2\Omega$. R_p and C_p are calculated from eq.(12)
231 and eq.(13). $Q_{sw}=100$ in the analyzed cases. The simulation results of Fig.
232 10 show the impact on the drain current of the GaN-HEMT transistor when
233 SRF is evaluated for 30MHz and 250MHz. These results depicts the increas-
234 ing in the drain current by around 50% which lead to an increase in
235 the switching losses by around 20%. This phenomenon is mainly generated
236 by the increase of the parasitic capacitance C_p when the SRF parameter is
237 lower.

238

Figure 10: Impact of the SRF on the drain current. Color nomenclature: blue - drain current for $SRF=250\text{MHz}$, red - drain current for $SRF=30\text{MHz}$.

239 Fig. 11 depicts the frequency behavior of the associated inductor losses
240 R_f and the quality factor Q_f for a power inductor of $8.2\mu\text{H}$, $Q(30\text{MHz}) = 100$
241 and $SRF = 250\text{MHz}$. Fig. 12 shows the inductor current for the aforemen-
242 tioned specifications in comparison with an ideal inductor. The frequency
243 distribution of power losses are plotted in Fig. 13. This figure shows that

244 the selected inductor drastically decreases the power losses at the switching
 245 frequency.
 246

Figure 11: Frequency behavior of R_f and Q_f for the modeled inductor.

Figure 12: Inductor current. Color nomenclature: blue – ideal inductor with low series resistance, red – power inductor considering $Q(30\text{MHz}) = 100$ and $SRF = 250\text{MHz}$.

247 The proposed analysis for power inductors has been described through
 248 this document. The simulated results have shown a suitable trade-off be-
 249 tween power and frequency performance. Next section will introduce the
 250 experimental setup to validate the proposed approach.

Figure 13: Inductor power distribution in the frequency-domain for $Q(30\text{MHz})=100$ and $SRF = 250\text{MHz}$.

251 5. Experimental results

252 This section describes the performed tests. First, the power inductors
 253 are measured and the circuital models are validated. Then, an experimental
 254 setup allows verifying the described power equivalence between the time and
 255 frequency domains. Finally, an experimental boost converter provides results
 256 about the performance of a conventional power inductor in a relative high-
 257 frequency.

258 5.1. Inductor circuital model and characterization

259 This test employs an impedance analyzer Agilent 4294A to measure the
 260 parameters of several power inductors. The impedance analyzer sweeps the
 261 frequency from 40Hz to 110MHz and it measures $Z - \theta$, $R - X$ and $L - Q$.
 262 Table 1 summarizes the measured and calculated parameters. R_p and C_p
 263 calculated from eq.(12) to eq.(13) selecting the Q factor at 10MHz in all
 264 cases. Fig. 14 depicts the simulated and measured R_f (the real part of the
 265 inductor impedance) for the inductor SRP5015TA. The MAPE (Mean Ab-
 266 solute Percentage Error) evaluates the model accuracy using eq.(14) where
 267 M_K is the measured value and S_k is the simulated value. As listed in Table
 268 1, the MAPE shows a partial agreement between the experimental data and
 269 the circuital model.

270

$$MAPE = \frac{1}{n} \sum_{k=1}^n \left| \frac{M_k - S_k}{M_k} \right| \quad (14)$$

271

272

273

274

275

276

277

However, Fig. 14 allows concluding that values for frequencies farther to the selected Q at 10MHz have less agreement than values around the selected Q . Therefore, the circuital model can slightly lose accuracy in a wide range of frequencies.

Table 1: Characterization and modeling of inductors

Inductor Ref.	Measure			Calculation			MAPE
	L (μH)	R_s ($\text{m}\Omega$)	Q (10MHz)	SRF (MHz)	R_p ($\text{K}\Omega$)	C_p (pF)	
SRP5015TA-8R2M	7.8	190	25.5	24.2	15.3	5.6	0.28
SRR1210-8R2Y	7.3	4.1	15.4	21.1	9.1	7.9	0.27
7447713082	7.7	29	13.2	29.8	7.2	3.7	0.28
744314850	8.2	24	7.7	35.4	4.3	2.5	0.15

Figure 14: Real part of inductor impedance (R_f). Inductor reference SRP5015TA-8R2M.

278 5.2. Inductor power in the time-domain and the frequency-domain

279 In this experimental setup, a waveform generator (33612A Keysight) pro-
 280 vides a square signal of 5Vpp to the inductor under test. The current probe
 281 (Tektronix CT2) measures the inductor current, and the active probe(RT-
 282 ZS20 R&S) measures the voltage. The oscilloscope (RTO-1044 R&S) records
 283 the waveforms and calculates the average power in the time domain and the
 284 inductor current FFT (Fast Fourier Transform) in the frequency domain.
 285 The test is carried out at 10MHz and 30MHz. The aim of this test is to
 286 validate the power equivalence using the proposed approach.

287
 288 Fig. 15 depicts the waveforms for square signals of case (a) for 10MHz
 289 and case (b) for 30MHz for the power inductor SRP5015A. In the case (a),
 290 the fundamental frequency is lower than the *SRF*. Therefore, the inductor
 291 is able to store energy as a magnetic field with relative low power loss. In
 292 contrast, the case (b) has a fundamental frequency higher than the *SRF*. As
 293 result, the inductor behaves as a capacitor distorting the current signal and
 294 increasing the power loss.

295
 296 Fig. 16 shows the FFT for the inductor current of case (a) in Fig. 15a.
 297 In Table 2, the contribution of each harmonic is calculated from the measured R_f
 298 (see Fig. 14) and the FFT (see Fig. 16) for the fundamental and
 299 harmonic frequencies using expression eq.(15). Results from Fig. 15a and
 300 Table 2 agree with the expected correlation between the power in the time
 301 and frequency domains.

$$P_{AVG} = \frac{1}{T} \int_0^T i(t)v(t) dt = \sum_{n=0}^N I_n^2 R_f \quad (15)$$

302
 303
 304
 Table 2: Inductor power frequency-domain (SRP5015A). Test at 10MHz - square signal.

Freq.(MHz)	0	10	30	50	70	90	Total
$P_h(\mu W)$	0.03	197	14	4.8	2.9	1.7	220

Figure 15: Test inductor SRP5015A at 10MHz and 30MHz.

Figure 16: FFT of inductor current for test at 10MHz - square signal. Inductor reference SRP5015A.

305 Table 3 summarizes the power results for the measured inductors. These
 306 results confirm the duality between the inductor power in the time-domain
 307 and the frequency-domain. However, differences between theoretical and
 308 experimental results are mainly caused by the shifting of the SRF given the
 309 parasitic capacitance and inductance of the current and voltage probes.

310 5.3. Boost converter at 1MHz

311 This test implements a boost converter at 1MHz. The boost converter
 312 specification are $V_{in}=30\text{V}$, $V_{out}=60\text{V}$, $P_{out}=40\text{W}$, and inductor current $I_L=1.5\text{A}$

Table 3: Inductor power in the time and frequency

	SRP5015TA-8R2M		SRR1210-8R2Y	
	10MHz	30MHz	10MHz	30MHz
Power time (μW)	239	848	257	925
Power freq. (μW)	220	760	235	857

	7447713082		744314850	
	10MHz	30MHz	10MHz	30MHz
Power time (μW)	285	1380	299	818
Power freq. (μW)	262	1140	283	767

313 considering an efficiency $\eta=0.9$. The design uses and inductor SRR1210-8R2
 314 given its favorable quality factor $Q(1\text{MHz})=30$ and $SRF=22\text{MHz}$. The se-
 315 lected inductor SRR1210-8R2 has a series resistance $R_s=17\text{m}\Omega$ and a sat-
 316 uration current of 7.5A. The switching frequency is set to 1MHz to ensure
 317 the eight harmonic lower than the SRF . A GaN-HEMT is used as a switch-
 318 ing device. The achieved results harmonize with the theoretical framework.
 319 However, the slight deviation between the temporal and frequency responses
 320 can be overcome by improving the experimental setup decreasing the para-
 321 sitic elements.

322

Figure 17: Experimental results for 1MHz boost converter. Inductor SRR1210-8R2. $P_{avg}=492\text{mW}$.

323 Fig. 17 shows the inductor waveforms. The inductor average power in the
 324 time-domain is $P_{avg}=492\text{mW}$. Fig. 18 depicts the harmonic spectrum for the
 325 inductor current. Table 4 lists the power contribution of each harmonic to
 326 the total power. The total power in the frequency-domain is $P_{avg}=447\text{mW}$.
 327 Results from Fig. 17 and Table 4 validate the equivalence between the power
 328 in the time and frequency domains. In additions, the results allow identifying
 329 that the behavior at the fundamental frequency is the main cause of the
 330 inductor power loss.

Figure 18: FFT for the inductor current of 1MHz boost converter.

Table 4: Inductor power in the frequency domain

Freq.(MHz)	0	1	2	3	4	5	Total
$P_h(\text{mW})$	14	418	0.4	11	0.05	2.7	447

331 5.4. Boost converter for 400V - 400W at 30MHz

332 This section shows the results of implementing a high-frequency boost
 333 converter. A power inductor was designed for this experimental setup. The
 334 designed inductor has specifications of $L=8\mu\text{H}$, $I_{sat}=3.5\text{A}$, $Q(30\text{MHz})=25$
 335 and $SRF=200\text{MHz}$. The switching device is a GaN-HEMT.

336

337 The boost converter is tested first at $V_{out}=60\text{V}$ - $P_{out}=10\text{W}$ and after at
 338 $V_{out}=400\text{V}$ - $P_{out}=400\text{W}$. The test is carried out first in relative low power
 339 to use available current probe (Tektronix CT2) because current probes for

340 high-current, high-voltage and high-frequency are currently under develop-
 341 ment. This represents a research challenge. In the second case, the inductor
 342 current is not measure for previous reasons. However, the global power con-
 343 verter results shows the suitable performance of the designed inductor.

344

345 In the first test, the specifications of the boost converter are $V_{in}=30V$,
 346 $V_{out}=60V$, and $P_{out}=10W$ at 30MHz. Fig. 19 shows the waveforms for the
 347 power inductor. In this case, the average power was $P_{avg}=780mW$ in the
 348 time-domain and $P_{avg}=700mW$ in the frequency-domain.

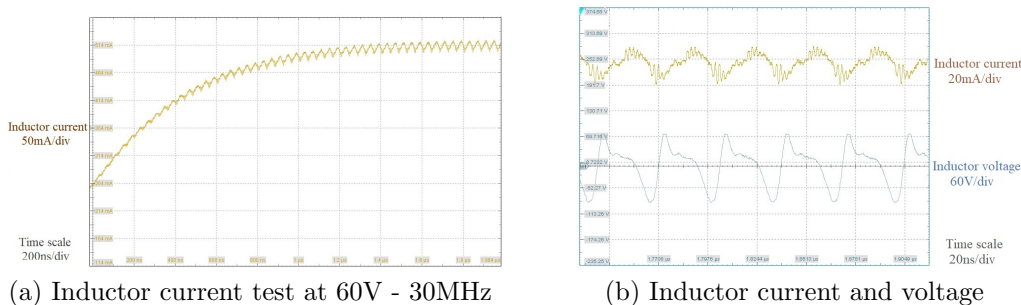

Figure 19: Inductor current and voltage for boost converter 60V - 10W at 30MHz

Figure 20: Experimental setup boost converter 400V - 400W at 30MHz.

349 For the second test, the implemented high-frequency boost converter has
 350 specifications of $V_{in}=200V$, $V_{out}=400V$, $P_{out}=400W$ at 30MHz. Fig. 20 shows
 351 the experimental setup for the high-frequency boost converter. Additionally,
 352 result of Fig. 21 depicts the behavior of the output voltage. As shown in Fig.
 353 21, the designed boost converter is able to increase the input voltage from
 354 200V to 400V with an output load of 400W. The switching frequency is set to
 355 30MHz to assess the GaN-HEMT devices at high-voltage and high-frequency
 356 given a suitable performance. As a consequence, these results confirm the

357 pertinence of the developed modeling approach to analyze and design power
 358 inductors to take advantages of the switching characteristics of GaN-HEMT
 359 devices.

361 6. Conclusions

362 The reported methodology has associated the analysis in the time and
 363 frequency domains for inductors in power converters using an extension of
 364 the Parseval's theorem. The proposed approach is complementary to con-
 365 ventional methodologies for the design of power converters. This analysis
 366 methodology allowed determining suitable criteria for the selection and sim-
 367 ulation of inductors according to expected power losses. The proposed ap-
 368 proach allowed disaggregating the power losses in the frequency-domain for
 369 complex inductor power signals in the time-domain. The study of the quality
 370 factor Q allowed concluding that increasing considerably Q has low impact
 371 on the power losses since the reduction in power losses becomes negligible.
 372 Therefore, a moderate Q factor can be selected to achieve a trade-off between
 373 inductor performance and manufacturing feasibility. Additionally, the Self
 374 Resonance Frequency SRF around eight times the switching frequency is a
 375 suitable criterion to avoid inductor current distortion. The proposed model
 376 in this work included frequency parameters of inductors in the design process
 377 of power converters. The experimental results have validated the proposed
 378 approach. However, the experimental setup should decrease the parasitic
 379 inductance and capacitance to minimize the measurement disturbances at
 380 high-frequency.
