#### Summary

This work explores methods for verifying the properties of Binary Neural Networks (BNNs), focusing on robustness against adversarial attacks. Despite their lower computational and memory needs, BNNs, like their full-precision counterparts, are also sensitive to input perturbations. Established methods for solving this problem are predominantly based on Satisfiability Modulo Theories (SMT) and Mixed-Integer Linear Programming (MILP) techniques, which often face scalability issues. We introduce an alternative approach using Semidefinite Programming (SDP) relaxations derived from sparse Polynomial Optimization (POP). Our approach, compatible with continuous input space, not only mitigates numerical issues associated with floating-point calculations but also enhances verification scalability through the strategic use of tighter first-order semidefinite relaxations. We demonstrate the effectiveness of our method in verifying robustness against both  $\|.\|_{\infty}$  and  $\|.\|_2$ -based adversarial attacks.

Keywords: Binary Neural Networks, Robustness Verification, Sparse Polynomial Optimization, Semidefinite Programming

#### **Binary Neural Networks**

Let  $L \geq 1$  be the number of hidden layers of a classifying BNN, with layer widths being given by  $\boldsymbol{n} = (n_0, n_1, \dots, n_L, n_{L+1})^{\mathsf{T}} \in \mathbb{N}^{L+2}$ , where  $n_0$  and  $n_{L+1}$  are input and output dimensions. A feed-forward BNN is a mapping from the input region  $\mathcal{R}_{n_0} \subset \mathbb{R}^{n_0}$  to the output set  $[\![1, n_{L+1}]\!]$  realized via successive compositions of several internal blocks  $(\mathbf{B}_i)_{i=1,\dots,L}$  and an output block  $\mathbf{B}_o$ :

$$\mathsf{BNN}: \mathcal{R}_{n_0} o \llbracket 1, n_{L+1} 
rbracket$$
  $\boldsymbol{x}^0 \mapsto \mathsf{BNN}(\boldsymbol{x}^0) := \mathsf{argmax} \left( \mathbf{B}_o(\mathbf{B}_L(\dots(\mathbf{B}_1(\boldsymbol{x}^0)))) \right).$  (1)

For any  $i \in [1, L]$ , the internal block  $\mathbf{B}_i$  implements successively three different operations: affine transformation, batch normalization and point-wise binarization, so that its output vector, denoted by  $\mathbf{x}^i$ , belongs to  $\{-1,1\}^{n_i}$ . These operations are described by a set of trainable parameters:

$$(\mathbf{W}^{[i+1]}, \mathbf{b}^{[i+1]})_{i \in [0,L]} \in \{-1,0,1\}^{n_{i+1} \times n_i} \times \mathbb{R}^{n_{i+1}}, \ (\boldsymbol{\gamma}^{[i]}, \boldsymbol{\beta}^{[i]}, \boldsymbol{\mu}^{[i]}, \boldsymbol{\sigma}^{2,[i]})_{i \in [1,L]} \in (\mathbb{R}^{n_i})^4.$$
 (2)

Steps	Input	Output	Transformation			
Linearization	$\boldsymbol{x}^{i-1} \in \{-1,1\}^{n_{i-1}}$	$oldsymbol{y} \in \mathbb{R}^{n_i}$	$oldsymbol{y} = oldsymbol{W}^{[i]} oldsymbol{x}^{i-1} + oldsymbol{b}^{[i]}$			
Batch-Normalization	$oldsymbol{y} \in \mathbb{R}^{n_i}$	$oldsymbol{z} \in \mathbb{R}^{n_i}$	$z_j = oldsymbol{\gamma}_j^{[i]} \left( rac{y_j - oldsymbol{\mu}_j^{[i]}}{\sqrt{oldsymbol{\sigma}_j^{2,[i]} + \epsilon}}  ight) + oldsymbol{eta}_j^{[i]}$			
Binarization	$oldsymbol{z} \in \mathbb{R}^{n_i}$	$x^i \in \{-1, 1\}^{n_i}$	$oldsymbol{x}^i = sign(oldsymbol{z})$			

**Table 1:** Structure of an internal block  $\mathbf{B}_i$ .

The output block  $\mathbf{B}_o$  applies a softmax transformation to the affinely-transformed outputs of the last hidden layer, i.e., for each  $j \in [1, n_{L+1}]$ ,

$$m{x}_{j}^{L+1} = rac{\exp(z_{j})}{\sum_{k=1}^{n_{L+1}} \exp(z_{k})}, \text{ where } z_{j} = m{W}_{(j:,)}^{[L+1]} m{x}^{L} + m{b}_{j}^{[L+1]}.$$
 (3)

### Sparse SDP for BNN Robustness Verification

Consider a sequence of vector-valued functions  $(m{h}_i, m{g}_i)_{i \in \llbracket 1, L 
rbracket}$  such that

$$m{x}^i := ext{sign}\left(m{W}^{[i]}m{x}^{i-1} + m{b}^{[i]}
ight) \implies egin{cases} m{h}_i(m{x}^i) := m{x}^i\odot m{x}^i - \mathbf{1} = \mathbf{0}, \ m{q}_i(m{x}^i, m{x}^{i-1}) := m{x}^i\odot (m{W}^{[i]}m{x}^{i-1} + m{b}^{[i]}) > m{0}, \end{cases}$$
 (4a)

Suppose that the input perturbation region  $B \subseteq \mathbb{R}^{n_0}$  can be encoded via positivity conditions on (at most quadratic) polynomials  $x^0 \mapsto g_B(x^0)$ . Then, the *standard* form BNN verification problems becomes:

$$\left(\min_{\boldsymbol{x}^0,\boldsymbol{x}^1,\dots,\boldsymbol{x}^L} f(\boldsymbol{x}^0,\boldsymbol{x}^1,\dots,\boldsymbol{x}^L)\right) \tag{5a}$$

$$\tau := \begin{cases} \text{s.t.} & \boldsymbol{h}_i(\boldsymbol{x}^i) = \boldsymbol{0}, \ i \in \llbracket 1, L \rrbracket, \\ & \boldsymbol{g}_i(\boldsymbol{x}^i, \boldsymbol{x}^{i-1}) \geq \boldsymbol{0}, \ i \in \llbracket 1, L \rrbracket, \\ & \boldsymbol{g}_{\boldsymbol{B}}(\boldsymbol{x}^0) \geq \boldsymbol{0}, \end{cases} \tag{5b}$$

where f is linear/quadratic, e.g.,  $f = f_k^{\mathrm{adv}}(\boldsymbol{x}^0, \boldsymbol{x}^1, \dots, \boldsymbol{x}^L) := \langle \boldsymbol{W}_{(\bar{v}:.)}^{[L+1]} - \boldsymbol{W}_{(k:.)}^{[L+1]}, \boldsymbol{x}^L \rangle + \boldsymbol{b}_{\bar{y}}^{[L+1]} - \boldsymbol{b}_k^{[L+1]}.$ 

#### **Exploiting Sparsity**

Let us suppose that  $[1, n] =: I_0 = \bigcup_{k=1}^p I_k$  with  $I_k$  not necessarily disjoint. The subsets  $I_k$ , called *cliques*, correspond to the subsets of variables  $\boldsymbol{x}_{I_k} := \{x_i, i \in I_k\}$ . An instance of the BNN robustness verification problem of the form (5) exhibits *correlative sparsity* since

- lacksquare There exist  $(f_k)_{k\in \llbracket 1,p
  rbracket}$  such that  $f=\mathbf{x}_k^pf_k$ , with  $f_k\in \mathbb{R}[m{x}_{I_k}]$ ,
- The polynomials  $\boldsymbol{g}$  can be split into disjoints sets  $J_k$ , such that  $\boldsymbol{g}_i(\cdot)_j \in J_k$  if and only if  $\boldsymbol{g}_i(\cdot)_j \in \mathbb{R}[\boldsymbol{x}_{I_k}]$ . Moreover,  $\boldsymbol{g}_{\boldsymbol{B}} \in J_k$  for  $k \in [\![1,p]\!]$ . Since  $\boldsymbol{h}_i(\cdot)_j$  only depends on  $\boldsymbol{x}_j^i$ , the overall sparsity structure is induced by inequality constraints that mimic the cascading BNN structure.

The hierarchy of correlatively sparse SDP relaxations is then given by

$$\boxed{\tau_{\text{CS}}^d := \sup_{\boldsymbol{\lambda}, \boldsymbol{\sigma}} \{\boldsymbol{\lambda} \in \mathbb{R} \mid f - \boldsymbol{\lambda} - \sum_{k=1}^p \boldsymbol{\sigma_k} \in \mathcal{I}_d(\boldsymbol{h}), \boldsymbol{\sigma_k} \in \mathcal{Q}_d(\{\boldsymbol{g}_i(\cdot)_j \in J_k\})\}.}$$

# Deriving a Tighter First-Order Relaxation - $au_{ m tighter,cs}^1$

 $\implies$  For each  $i \in [1, L]$ , we replace the constraint defined in (4b) by the following two constraints:

$$\left[\tilde{\boldsymbol{g}}_{i}^{1}(\boldsymbol{x}^{i},\boldsymbol{x}^{i-1}):=(\boldsymbol{x}^{i}+\boldsymbol{1})\odot\left(\boldsymbol{W}^{[i]}\boldsymbol{x}^{i-1}+\boldsymbol{b}^{[i]}\right)\geq\boldsymbol{0},\tag{6a}$$

$$\left(\tilde{\boldsymbol{g}}_{i}^{2}(\boldsymbol{x}^{i}, \boldsymbol{x}^{i-1}) := (\boldsymbol{x}^{i} - \mathbf{1}) \odot \left(\boldsymbol{W}^{[i]} \boldsymbol{x}^{i-1} + \boldsymbol{b}^{[i]}\right) \ge \mathbf{0}.$$
 (6b)

 $\longrightarrow$  Add the following two *redundant* quadratic constraints, i.e., *tautologies*, to the optimization problem (5):

$$\left(\tilde{\boldsymbol{g}}_{i}^{\mathsf{t}1}(\boldsymbol{x}^{i}, \boldsymbol{x}^{i-1}) := (\boldsymbol{x}^{i} + \mathbf{1}) \odot \left(\operatorname{nv}\left(\boldsymbol{W}^{[i]}\right) - \boldsymbol{W}^{[i]}\boldsymbol{x}^{i-1}\right) \ge \mathbf{0},\tag{7a}$$

$$\begin{cases} \tilde{\boldsymbol{g}}_{i}^{\mathsf{t2}}(\boldsymbol{x}^{i}, \boldsymbol{x}^{i-1}) := (\mathbf{1} - \boldsymbol{x}^{i}) \odot \left(\operatorname{nv}\left(\boldsymbol{W}^{[i]}\right) + \boldsymbol{W}^{[i]}\boldsymbol{x}^{i-1}\right) \geq \mathbf{0}, \tag{7b} \end{cases}$$

## Theorem

For any BNN verification problem,  $\tau_{\text{tighter,cs}}^1 = \tau_{\text{tighter}}^1 \geq \tau^1$ . If  $L \geq 2$ , there exists an affine f such that the inequality is strict. We also have  $\tau_{\text{tighter,cs}}^1 \geq \tau_{\text{LP}}$  for any affine f.

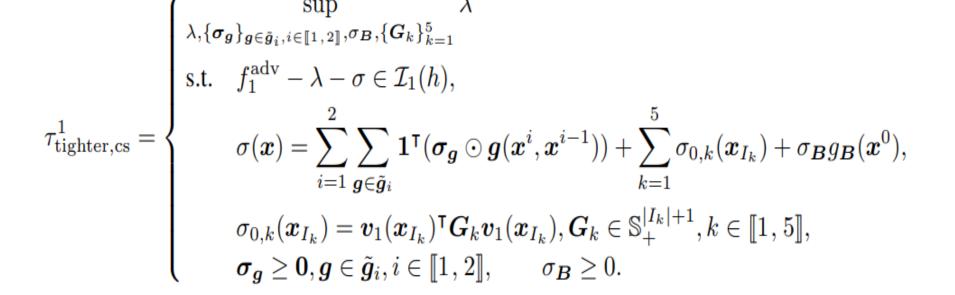

Figure 1: (left) A toy BNN with L=2 and  $(n_0,n_1,n_2,n_3)=(3,2,2,2)$ . The cliques  $I_1,I_2,I_3$  (red polygons) and  $I_4,I_5$  (blue polygons) are used to compute  $\tau^1_{\text{tighter,cs}}$  (right). We let  $\tilde{\boldsymbol{g}}_i=\{\tilde{\boldsymbol{g}}_i^1,\tilde{\boldsymbol{g}}_i^2,\tilde{\boldsymbol{g}}_i^{\dagger 1},\tilde{\boldsymbol{g}}_i^{\dagger 2}\}$ .
